Forgotten Books. Paperback. Condition: New. This item is printed on demand. Dimensions: 9.0in. x 6.0in. x 0.1in.Excerpt from Third Annual Conference of the Woods Department, Held at Berlin, New Hampshire, November 23 and 24, 1915 This is a dangerous forest parasite and occurs thruout Europe and America. It is found on most species of pine, also on spruce, hemlock, fir and tamarack. The sapwood of the pine is not attacked but on the others both sapwood and heartwood are affected. The external appearance of the disease is evidenced by the dripping of resin from wounds and old branch stubs. The sporophores (fruiting bodies) on pine, spruce and fir, appear mostly at points where branches are broken off, forming clusters. On the fir, they may appear anywhere on the trunk. The resin contents being higher on the Spruce, may account for sporophores being found more commonly on the stubs of old branches. In appearance the sporophores are hard, woody, brown or black, and deeply ridged. They are often hoof-shaped but vary greatly. The upper surface is rough and deeply ridged and continues to form annual zones for a number of years. The under or fruiting surface is made up of tubes or pores which are lined with basidia (microscopic projections) which bear four elliptical spores on stalks. The spores (which correspond to seeds in the higher plants) are carried by the wind, birds or insects to the broken branches or other wounds. With proper conditions of moisture they germinate, sending out slender filaments called mycelium. The mycelium spreads through branch and stem, particularly upward and downward in the same year ring. In this way longitudinal and peripheral zones are formed in the wood, giving rise to the popular name ring scale. Single hyphae (hair like filaments) bore through the cell walls,...
