Springer. Paperback. Condition: New. 179 pages. Dimensions: 9.0in. x 6.1in. x 0.6in. Single-molecule techniques eliminate ensemble averaging, thus revealing transient or rare species in heterogeneous systems 13. These approaches have been employed to probe myriad biological phenomena, including protein and RNA folding 46, enzyme kinetics 7, 8, and even protein biosynthesis 1, 9, 10. In particular, immobilization-based fluorescence techniques such as total internal reflection fluorescence microscopy (TIRF-M) have recently allowed for the observation of multiple events on the millisecond to seconds timescale 1113. Single-molecule fluorescence methods are challenged by the instability of single fluorophores. The organic fluorophores commonly employed in single-molecule studies of biological systems display fast photobleaching, intensity fluctuations on the millisecond timescale (blinking), or both. These phenomena limit observation time and complicate the interpretation of fluorescence fluctuations 14, 15. Molecular oxygen ( $O_2$ ) modulates dye stability. Triplet  $O_2$  efficiently quenches dye triplet states responsible for blinking. This results in the formation of singlet oxygen 1618. Singlet  $O_2$  reacts efficiently with organic dyes, amino acids, and nucleobases 19, 20. Oxidized dyes are no longer fluorescent; oxidative damage impairs the folding and function of biomolecules. In the presence of saturating dissolved  $O_2$ , blinking of fluorescent dyes is suppressed, but oxidative damage to dyes and biomolecules is rapid. Enzymatic  $O_2$ -scavenging systems are commonly employed to ameliorate dye instability. Small molecules are often employed to suppress blinking at low  $O_2$  levels. This item ships from multiple locations. Your book may arrive from Roseburg, OR, La Vergne, TN. Paperback.
